Keywords:

CCTT, Mobility, M&S, ModSAF, NRMM, Terrain, Trafficability, Vehicle, WARSIM

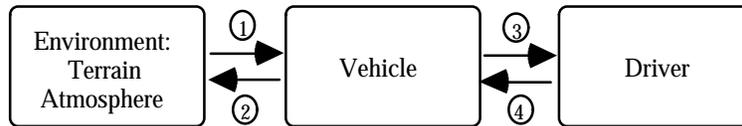

**ABSTRACT:** *The term "terrain trafficability" is commonly used to denote the terrain component of the environment which affects ground vehicle mobility. This document describes the terrain trafficability representations used in four ground vehicle mobility models for virtual and constructive simulation: MosSAF/SIMNET, CCTT, WARSIM, and NRMM II. It is a "work in progress" and can be expected to evolve as the community becomes more familiar with the nature and use of ground vehicle mobility models and the capabilities of ground vehicle mobility models mature.*

# 1. Introduction

## 1.1 Defining a Ground Vehicle Mobility Model

By the narrowest definition, a ground vehicle mobility model is concerned only with the effects on the vehicle caused by the interaction of the vehicle with the environment (arrow #1 in Figure 1, below). In general, however the definition should also include the effects on the:

- environment caused by the interaction of the vehicle with the environment (arrow #2)
- driver caused by the interaction of the vehicle with the driver (arrow #3)
- vehicle caused by the interaction of the vehicle with the driver (arrow #4)

**Figure 1: Vehicle Model Interactions**

All subsequent usage of the term “mobility modeling” in this document is intended to refer to wheeled and tracked ground vehicles as they interact with the environment and the vehicle driver. This document does not consider issues in modeling the ground mobility of soldiers or ground effect vehicles dependent on air cushions and fans for movement.

Both the terrain and atmosphere contribute to the interaction of the vehicle with the environment. The term “terrain trafficability” is commonly used to denote the terrain component of the environment which affects ground vehicle mobility. This document describes the terrain trafficability representations used in several common ground vehicle mobility models.

## 1.2 Motivation and Purpose

Several DoD organizations are currently developing, or have recently developed, ground vehicle mobility models for use in modeling and simulation (M&S). These models are not clearly consistent with either each other or the current Army mobility modeling standard: the NATO Reference Mobility Model II (NRMM) for a variety of reasons. These inconsistencies result from differences in the functional requirements for each model, in particular issues in the resolution, accuracy, and performance required for specific M&S applications.

Recognizing that M&S requirements vary by functional usage, it is important that the DoD work to standardize a family of mobility models for use in M&S with well-understood characteristics and ranges of applicability. Critical to that standardization process is the ability to characterize and classify ground vehicle mobility models in a manner that ensures that they are not applied to inappropriate tasks, potentially resulting in the generation of misleading or inaccurate analytic representations or results.

An important goal of this document is to bring together the developers of ground vehicle mobility models and the developers of M&S systems using these models (and their customer, the warfighter) in order to more closely couple the capabilities of ground vehicle mobility models with user requirements. The requirements of both virtual and constructive simulations are addressed.

Fidelity and performance are the basic measures of a ground vehicle mobility model. Virtual simulations require ground vehicle mobility models of relatively high fidelity and real-time performance; computer-generated force (CGF) simulations (both aggregate-level<sup>1</sup> and platform-level<sup>2</sup>) require models of low to moderate fidelity but significantly better than real-time performance. Characterizing these differences in required fidelity is a significant challenge for the M&S community. The differences in performance are more easily characterized.

<sup>1</sup> Aggregate level simulations generally model ground vehicles in groups, such as a company-sized unit; typically these groups are heterogeneous and typical doctrine requires cohesion in the group during maneuver. As a result, the group generally moves based on the most-constrained vehicle (e.g., slowest).

<sup>2</sup> Platform-level simulations model ground vehicles as individual entities, although the effects of attached components such as a plow or trailer are often combined into the entity model, rather than being treated separately.

### 1.3 Organization

This document describes the terrain trafficability representations used in four ground vehicle mobility models for virtual and constructive simulation: ModSAF/SIMNET, CCTT, WARSIM, and NRMM II. For each it provides system background, an overview of the model, and a specification of its terrain slope and trafficability representations. This document is a "work in progress" and can be expected to evolve as the community becomes more familiar with the nature and use of ground vehicle mobility models.

### 1.4 Terrain Factors

The major terrain trafficability factors which influence ground vehicle mobility are as follows.

- **Slope:** Includes aspect with respect to direction of travel.
- **Obstacle descriptions:** Cross-sectional geometry; generic models acceptable.
- **Surface materials:** Categorized (by definition). Continuously valued (e.g., different concrete or asphalt compositions) desirable but probably excessive for other than the highest fidelity settings.
- **Soil Type:** The soil types in the Unified Soil Classification System (USCS) are composed of two letter (or four letters in the case of a borderline soil) connotative symbols composed of a prefix and a suffix. The prefix indicates the main soil type and the suffix indicates subdivisions of these main groups, as shown in Table 1.

**Table 1:** USCS Soil Type Connotative Symbols

| Main Soil Type          | Symbol |
|-------------------------|--------|
| Gravel                  | G      |
| Sand                    | S      |
| Silt                    | M      |
| Organic silts and clays | O      |
| Peat                    | PT     |

| Gradation                  | Symbol |
|----------------------------|--------|
| Well-graded <sup>3</sup>   | W      |
| Poorly-graded <sup>4</sup> | P      |

| Liquid limit         | Symbol |
|----------------------|--------|
| Low LL ( $\leq 50$ ) | L      |
| High LL ( $> 50$ )   | H      |

These are combined to define 15 separate soil groupings, as shown in Table 2.

<sup>3</sup> Well-graded: soil materials characterized by a complete range of all representative grain sizes, and without excess or deficiency of any of these grain sizes.

<sup>4</sup> Poorly-graded: soil materials characterized by predominantly one grain size (these materials are commonly described as uniform graded) or a range of sizes with some intermediate sizes missing (these materials are sometimes described as gap-graded, skip-graded, or step-graded).

**Table 2: USCS Soil Types**

| USCS Code | Description   |
|-----------|---|
| GW        | Well-graded gravels                                       |
| GP        | Poorly-graded gravels                                     |
| GM        | Silty gravels   |
| GC        | Clayey gravels  |
| SW        | Well-graded sands   |
| SP        | Poorly-graded sands                                       |
| SM        | Silty sands   |
| SC        | Clayey sands  |
| ML        | Inorganic silts and very fine sands                       |
| MH        | Inorganic silts   |
| CL        | Inorganic clays of low to medium plasticity               |
| CH        | Inorganic clays of high plasticity                        |
| OL        | Organic silts and organic silty clays of low plasticity   |
| OH        | Organic clays of medium to high plasticity, organic silts |
| PT        | Peat and other highly organic soils                       |

- **Soil strength:** Characterized by several inter-related factors:
  - RCI: Remolding Cone Index.
  - Cohesion: "C".
  - Internal friction angle: "Phi" – related to shear strength of soil and angle of repose/slump.
  - Density
  - Moisture content
- **Freeze/thaw depths**
- **Surface roughness:** Statistical in nature; classed into RMS groupings.
- **Surface slipperiness/wetness/ice**
- **Snow:**
  - Type: Used to map to density, age, and layering.
  - Depth
- **Non-woody vegetation:** Vegetation with stem diameter less than 1.0 inches. Includes brush and crops.
  - Type: Needs to be resolved to type of crop; e.g. millet (thick base clump with single stalk) vs. wheat (simple shoots).
  - Density: Stems per unit area (affect override and resistance)
  - Direction: Require angle of rows to nearest of 8 cardinal directions.
  - Height: Potentially affects driver visibility.
- **Woody vegetation:**
  - Type: Species can be used to derive stem spacing distribution assuming a non-managed mature forest. Different algorithms are required for managed forests and particular species (e.g., loblolly pine).
  - Diameter: Either discrete values and/or statistical distribution.
  - Spacing: Used only for statistical modeling.
- **Hydrology:**
  - Depth

- Velocity
- Direction: If vehicle is buoyant, need to determine direction of drift.

The primary determinants of terrain trafficability in most settings are slope, surface material (including soils) type/strength, and vegetation. The secondary determinants are hydrology and localized natural and man-made obstacles (including structures).

## 2. ModSAF/SIMNET Trafficability

### 2.1 Background

The Modular Semi-Automated Forces (ModSAF) environment provides a Distributed Interactive Simulation (DIS) system for simulating and controlling battlefield entities, such as vehicles, Dismounted Infantry (DI), missiles, and dynamic structures on a virtual battlefield. These entities interact with each other and with manned individual entity simulators, such as an M1 tank simulator, to support training, combat development experiments, tactics and doctrine studies, weapon and sensor evaluations, and man-machine interface issues. The ModSAF System functions in an established simulation system environment at the Aviation Test Bed (AVTB) at Ft. Rucker, Alabama, and the Mounted Warfare Test Bed (MWTB) at Ft. Knox, Kentucky, among other locations.

ModSAF was initially developed by the Defense Advanced Research Projects Agency (DARPA) What If Simulation System for Advanced Research and Development (WISSARD) and "Seamless Simulation" programs. ModSAF restructures the SIMNET Semi-Automated Forces (SIMNET SAF 3.10.6 and ODIN SAF 4.3.6) baseline to make it more open, more modular, and DIS compliant. In addition to new functionality developed under WISSARD, ModSAF focused on providing better control, more flexibility, and extensions to higher echelons, and full documentation.

With ModSAF, the operator is able to organize forces according to task, transfer control to another operator, and regroup forces for new tasks. A single operator has the ability to command vehicles simulated by more than one SAF workstation. It is also possible to checkpoint and restart a mission without re-tasking forces. Command and control information is recorded along with exercise information. The system provides beyond visual range air-to-air combat behavior, and includes improved modeling of radar, indivisibility among entities, and detection probabilities. The operator can plan higher level and more flexible missions by including contingencies for known and expected agents. The resulting ModSAF initially ran under DIS 2.0.3 protocol standards, but has been subsequently upgraded to subsequent DIS protocol versions, and then ported to use the High Level Architecture (HLA) Run Time Infrastructure (RTI).

The ModSAF ground vehicle mobility model is unchanged from the SIMNET baseline. It serves as a good example of an emulated-driver vehicle model as used in platform-level CGF simulations. These have reduced fidelity requirements from human driver trainers, and are required to run at "faster than real time" speeds.

The model has been modified for use in the OneSAF Testbed (OTB; the designated successor to ModSAF) and the Joint SAF (JSAF), so the following descriptions may not exactly correspond to particular current implementations.

### 2.2 Model Overview

ModSAF uses a simple parametric formulation which characterizes vehicle performance according to vehicle type and 16 soil types. These six parameters are:

- Maximum speed forward (Kilometers/Hour)
- Maximum speed reverse (Kilometers/hour)
- Maximum acceleration (Meters/second<sup>2</sup>)
- Maximum deceleration (Meters/second<sup>2</sup>)
- Maximum turning rate (Arc Degrees/second)
- Maximum climb angle (Arc Degrees)

In addition, a fuel usage rate is specified for engine idle and maximum power.<sup>5</sup>

---

<sup>5</sup> E.g., 0.125 at engine idle, and 12.5 at maximum power; the units are undefined in the documentation.

For comparison purposes, Tables 3 through 8 list the parameters for six vehicles. These vehicles were chosen based on the CCTT vehicle classes (see Table 10) and their class-specific representative vehicles.

**Table 3:** Wheeled Low Mobility: US M977 model parameters

| Soil Type          | Max. Speed Forward (KPH) | Max. Speed Reverse (KPH) | Max. Accel. (MPS <sup>2</sup> ) | Max. Decel. (MPS <sup>2</sup> ) | Max. Turn Rate (DPS) | Max. Climb Angle (Degs) |

(•: generic to all tracked vehicles)

In summary, for these six specific cases:

- Of 16 soil types (see Section 2.4, below), only 6 are explicitly used. Of those, only 4 actually have differing effects on vehicle mobility: DEFAULT, RCI050, SHALLOW\_WATER, and DEEP\_WATER. The latter is always impassable. For passable soil types, there are essentially only 3 categories:

- Hard surface: always at maximum speed
- Soft surface: 60% or less of maximum speed
- Fordable: 40% or less of maximum speed
- Wheeled vehicle values have been copied from tracked vehicle values.
- Maximum rates of acceleration are constant across vehicle types.
- Maximum turn rates are constant across vehicle types.
- In all cases, maximum climb angle is as good or better in water than on dry land.

For specific analysis and training purposes it is not uncommon to edit vehicle-specific parameter files, including ensuring that important vehicles include parameters for important soil types. When appropriate soil types are not included in a vehicle parameter file, the values used are those of SOIL\_DEFAULT.

The basic approach used to calculate the actual speed of a vehicle is as follows:

- The desired speed for this vehicle is determined by the driver model (*desired\_speed*)
- The current speed is read from the vehicle model (*current\_speed*)
- The maximum speed for the vehicle type on the current soil type is read (*max\_mps*)
  - If the vehicle is towing another object, *max\_mps* is set to a maximum towing speed
  - If the vehicle is on an uphill slope, a multiplier effect is calculated which degrades *max\_mps*
- If the vehicle is crossing a bridge or breaching, *desired\_speed* is degraded based on parameters associated with the bridge or type of breach
- If the *desired\_speed* is greater than *max\_mps*, the *desired\_speed* is limited to *max\_mps*
- If the *current\_speed* is not equal to *desired\_speed*, acceleration or deceleration is taken into consideration:
  - *desired\_acceleration* is calculated as  $(desired\_speed - current\_speed) / dt$ .
  - If *desired\_acceleration* is less than the *maximum\_acceleration* on the current soil type
    - *current\_speed* is set to *desired\_speed*
  - Else
    - *current\_speed* is calculated as  $current\_speed + (maximum\_acceleration * dt)$

A similar approach is used for deceleration, and movement in reverse. Finally, there may then be further degradation of the vehicle speed, and the time it takes to complete the driver-specified path, due to presence of terrain obstacles that must be negotiated.

### 2.3 Slope

The ModSAF ground vehicle mobility model compares the slope value along the direction of vehicle travel, and if it exceeds a vehicle-specific maximum climb angle for the current soil type then the vehicle stops. Below the threshold, terrain slope has a multiplicative degradation effect on vehicle speed. High lateral slopes may cause tracked vehicles to “throw a track” and stop.

### 2.4 Trafficability

The ModSAF ground vehicle mobility model defines 16 surface types, called “soil types” (see Table 9) for modeling ground vehicle mobility. Each surface type denotes a qualitative surface strength, surface slipperiness, the presence of stemmed vegetation, the presence of overlying water, and the presence and depth of certain unique conditions.

**Table 9:** ModSAF Soil Types

| Index | Soil Type          | Description                   |
|-------|--------------------|-------------------------------|
| 0     | SOIL_DEFAULT       | Unknown type of soil          |
| 1     | SOIL_ROAD          | Asphalt or other hard surface |
| 2     | SOIL_RCI250        | Packed soil or dirt road      |
| 3     | SOIL_RCI050        | Soft sandy soil               |
| 4     | SOIL_DEEP_WATER    | Impassable deep water         |
| 5     | SOIL_SHALLOW_WATER | Passable shallow water        |

|                 |                    |  |
|-----------------|--------------------|--|
| 6               | SOIL_MUD           | Muddy soil                             |
| 7               | SOIL_MUDDY_ROAD    | Wet dirt road                          |
| 8               | SOIL_ICE           | Slick ice surface                      |
| 9               | SOIL_SWAMP         | Very soft surface                      |
| 10              | SOIL_FORESTED      | Canopy or forested area                |
| 11              | SOIL_US_RAILROAD   | Railroad w/ US specifications          |
| 12              | SOIL_EURO_RAILROAD | Railroad w/ European specs.            |
| 13              | SOIL_ROCKY         | Small rocks <= 18 inches               |
| 14              | SOIL_BOULDERS      | Large boulders 6 ft. high              |
| 15              | SOIL_FLIMSY        | Indoor surface for dismounted infantry |
| 15 <sup>8</sup> | SOIL_NO_GO         | Terrain that is not traversable        |

The ModSAF ground vehicle mobility model generally treats stemmed vegetation and localized terrain obstacles (e.g., anti-tank ditches) as discrete objects which are handled by either maneuvering (avoidance) or as a series of localized slopes. Snow does not currently affect ground vehicle movement in ModSAF.

### 3. CCTT Trafficability

#### 3.1 Background

The Close Combat Tactical Trainer (CCTT) is the first system in the Combined Arms Tactical Trainer (CATT) family of training systems. CCTT utilizes the Distributed Interactive Simulation (DIS) network protocol to provide a virtual environment for training armor and mechanized infantry personnel. CCTT is composed of a variety of manned modules, an Operations Center (OC), Semi-Automated Forces (SAF), and several support workstations.

The manned module vehicles (MMV) are cabin simulations with virtual out-the-window views for training on vehicles such as the M1A1, M1A2, and M113. The CCTT manned modules, OC, and SAF use the same terrain model to support mobility modeling.

SAF and OC provide emulated vehicles to populate the battlefield; they share a common CGF architecture. SAF provides a wide range of both BLUFOR (friendly) and OPFOR (enemy) entities. OC provides BLUFOR entities to support battalion staff training and to add depth to the battlefield with entities which provide resupply, maintenance, combat engineering, and fire support capabilities. Both SAF and OC are controlled via user interfaces provided on the SAF Workstations and OC Workstations, respectively. The actual simulation of the SAF and OC entities is provided by separate CGF processors dedicated to entity simulation.

The CCTT manned modules and SAF use the same terrain model to support ground vehicle mobility modeling, however the manned modules require a higher level of fidelity in order to support crew training. In order to preserve interoperability between the manned modules and the SAF, a more complex model of ground vehicle mobility is used in the CGF architecture than might be otherwise warranted.

The CCTT SAF ground vehicle mobility model is an emulated-driver vehicle model which while having reduced fidelity requirements from the associated manned module human driver trainers uses the same model of terrain trafficability. It is only required to run at "real time" speeds, as is the manned module.

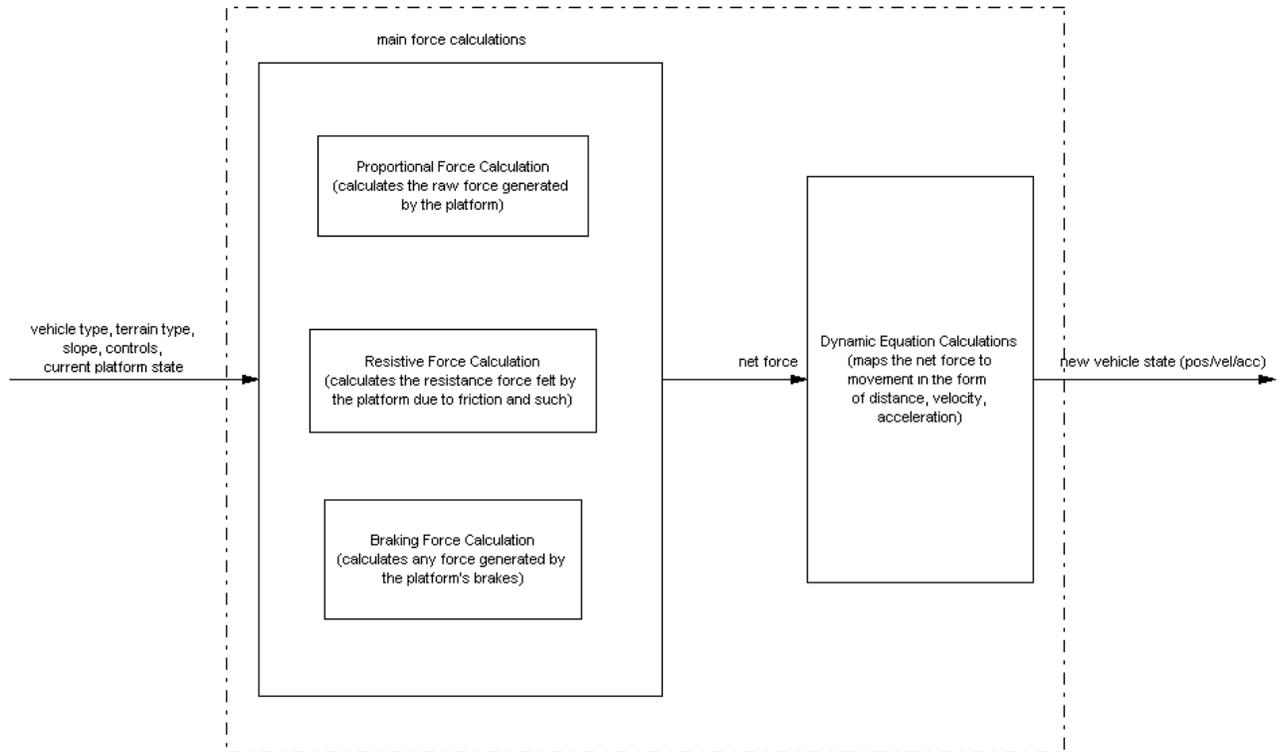

The model has been modified and enhanced subsequent to the initial fielding of CCTT, so the following descriptions may not exactly correspond to a particular implementation.

<sup>8</sup> Note that this index has two associated meanings, depending on the terrain database in which it appears.

### 3.2 Model Overview

The CCTT ground vehicle mobility model is based on a general first-principle dynamics model (see Figure 2).

#### Simple View of a Dynamic Model

**Figure 2:** General Dynamics Model Formulation

The model integrates explicit driver inputs (e.g., throttle, brake) with vehicle class-specific velocity, resistance force, and deceleration pre-computed curves (see Figures 3 and 4).

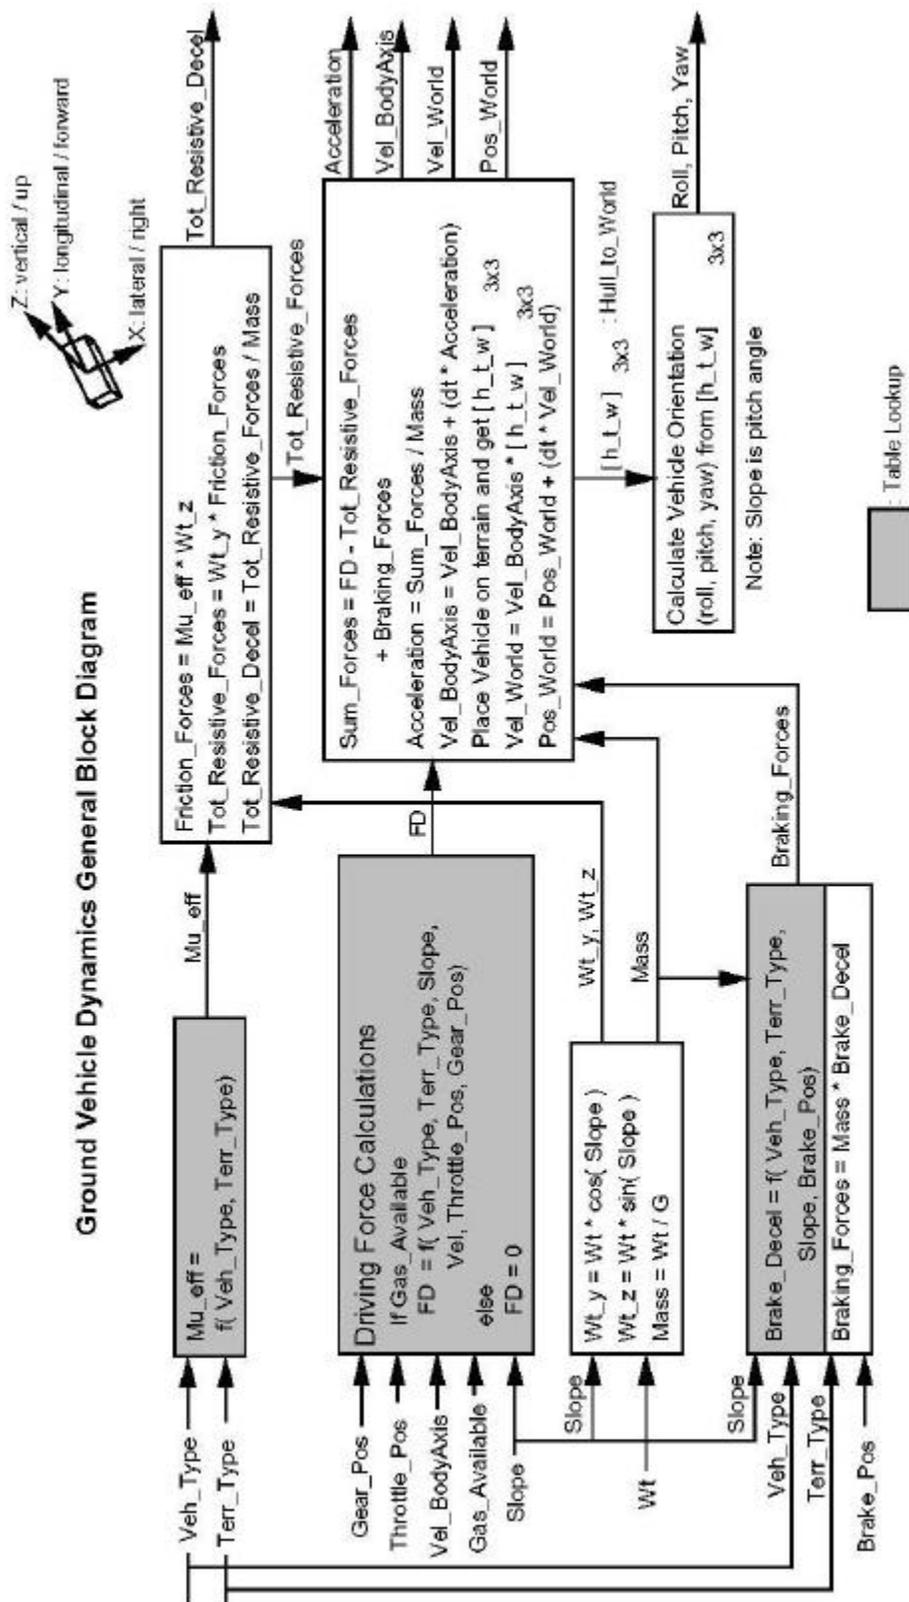

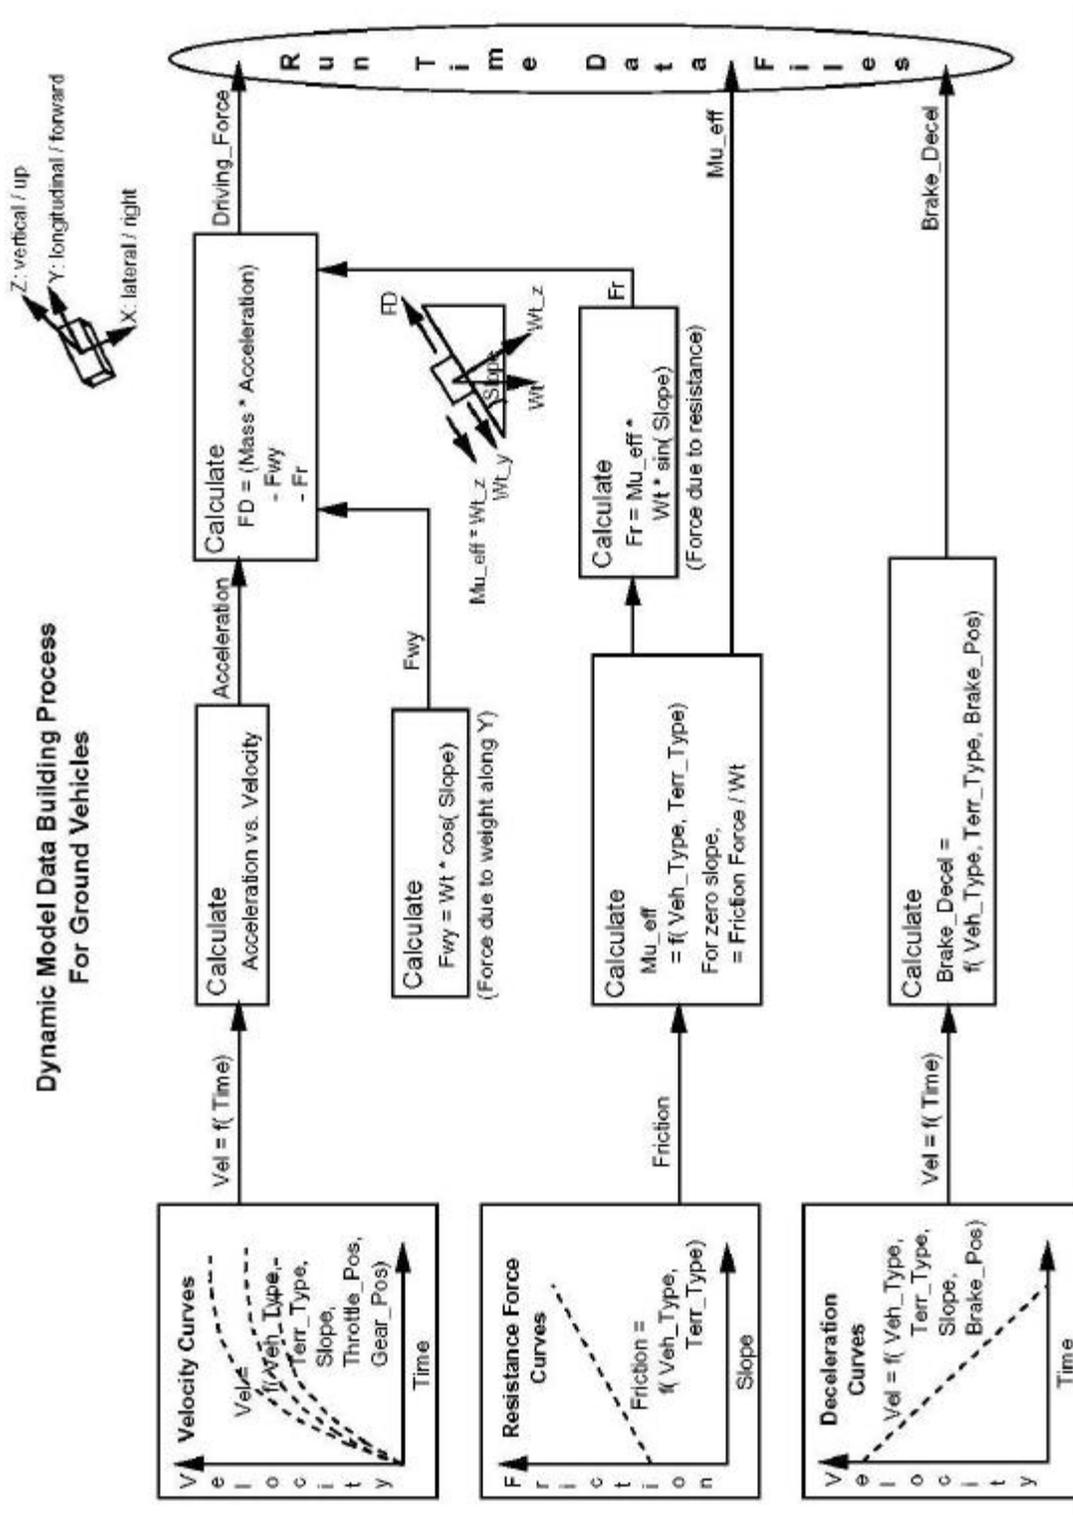

Figure 3: CCTT Vehicle Dynamics Block Diagram

**Figure 4:** CCTT Use of Velocity, Resistance Force, and Deceleration Curves

The various types of CCTT manned module vehicles are binned into 6 classes based on the ground-contact system used and general mobility characteristics (see Table 10). For each class, the three (velocity, resistance force, and deceleration) curves are pre-computed using NRMM for each of the 30 terrain codes (see Section 3.4, below).

**Table 10: CCTT Vehicle Classes**

| SAF Class                  | Representative Vehicle             | Other Vehicles in Class  |
|----------------------------|------------------------------------|--|
| Wheeled: Low Mobility      | M977 HEMTT<br>(10 Ton Cargo Truck) | M978 HEMTT FS, M984E1 HEMTT Wrecker, M985 HEMTT (10 Ton Cargo Truck), BRDM2 ATGW with 4 AT5, 2S12 120mm Mortar, GAZ-66 Truck, KRAZ Truck   |
| Wheeled: High Mobility     | M1025 HMMWV                        | M93 NBC Recon Vehicle, M1043 HMMWV, M1044 HMMWV, M106A2, M1064, M998 HMMWV, BRDM2, BTR 60P, M1078 LMTV, M1079 LMTV, M1083 MTV, M1089 MTV Wrecker, M1091 MTV, HMMWV with TOW Launcher, MTR 80, UAZ469 Medium Truck, French AMX 10 RAC           |
| Tracked: Low Mobility      | M60 Series AVLB                    | M728 CEV, M9 ACE, M88A1 Tank Recovery Vehicle, T62 w/o Reactive Armor, British Challenger MBT, British Chieftain MBT, French AMX 30 MBT  |
| Tracked: Moderate Mobility | M981 FISTV                         | M113A3 APC, M113A1 APC/Ambulance, M577A2 CP, GMZ Tracked Mine Layer, MTU-20 AVLB, MTK-2 Mine Clearer, BREM1 Recovery Vehicle, ZSU 23-4 Quad 23mm, 2S19 152mm Self-propelled Howitzer, 2S3 152mm Self-propelled Howitzer, 2S6 Quad 30mm 8 SA 19 |
| Tracked: Good Mobility     | M2A2 BFVS                          | M992 FAASV, M109A6 Self-propelled Howitzer, M270 MLRS, BMPIKsh, BMPIP, SA-13 Air Defense Missile Artillery, BAT-2 Route Clearing Vehicle, SA-15 Air Defense Missile Artillery, T64/T64B w/Reactive Armor, 2S1 122mm Self-propelled Howitzer    |
| Tracked: High Mobility     | M1A1 MBT                           | T80, BMPII, BMPIII, 9P149 (MTLB w/AT6), 1V12 MT-LB Variant (Jamming Variant), German Leopard II MBT, German Marder2, T72, French AMX 40 LeClerc MBT, Leopard IA4, British Warrior  |

### 3.3 Slope

The CCTT ground vehicle mobility model defines 11 slope classes (see Table 11). Each class represents a range of slope values along the direction of vehicle travel, and is treated as a single representative slope in the ground vehicle mobility model.

**Table 11: CCTT Slope Classes**

| Slope Class | Slope Range (Percent) | Representative Slope (Percent) |
|-------------|-----------------------|--------------------------------|
| 1           | <= (- 60)             | - 60                           |
| 2           | - (40 - 60)           | - 50                           |
| 3           | - (20 - 40)           | - 30                           |
| 4           | - (5 - 20)            | - 13                           |
| 5           | - (0 - 5)             | - 3                            |
| 6           | 0                     | 0                              |

|    |         |    |
|----|---------|----|
| 7  | 0 - 5   | 3  |
| 8  | 5 - 20  | 13 |
| 9  | 20 - 40 | 30 |
| 10 | 40 - 60 | 50 |
| 11 | >= 60   | 60 |

### 3.4 Trafficability

The CCTT ground vehicle mobility model defines 30 terrain codes (see Table 12) for modeling ground vehicle mobility and designates an associated correlation from the material codes used in the image generator for the manned modules. Each terrain code denotes a surface type (generally soil), both qualitative and quantitative surface strengths, surface slipperiness, the presence of non-stemmed vegetation, and the presence and depth of overlying water.

**Table 12: CCTT Terrain Codes**

| Terrain Code | USCS Soil Type or Surface Type                 | Qualitative Soil Strength     | CI / RCI |
|--------------|--|-------------------------------|----------|
| 1            | SP, SW   | Soft                          | 35       |
| 2            | SP, SW   | Average                       | 100      |
| 3            | SP, SW   | Hard                          | 130      |
| 4            | SM, SC, ML, ML, CH, MH, OL, OH                 | Very Soft                     | 25       |
| 5            | GW, GP, GM, GC, SM, SC, CL, ML, CH, MH, OL, OH | Soft                          | 35       |
| 6            | SM, SC, CL, ML, CH, MH, OL, OH                 | Average - Soft                | 50       |
| 7            | SM, SC, CL, ML, CH, MH, OL, OH                 | Average - Hard                | 80       |
| 8            | SM, SC, CL, ML, MH, OL                         | Hard                          | 130      |
| 9            | GW, GP, GM, GC, SM, SC, CL, ML, MH, OL         | Very Hard                     | 280      |
| 10           | SM, SC, CL, ML, MH, OL                         | Hard (Slippery)               | 130      |
| 11           | SM, SC, CL, ML, MH, OL                         | Very Hard (Slippery)          | 280      |
| 12           | CH, OH   | Hard                          | 130      |
| 13           | CH, OH   | Very Hard                     | 280      |
| 14           | CH, OH   | Hard (Slippery)               | 130      |
| 15           | CH, OH   | Very Hard (Slippery)          | 280      |
| 16           | PT   | Dry Peat                      | 40       |
| 17           | GW, GP, GM, HC, Rock                           | Dry Loose Surface Road        | 300      |
| 18           | GW, GP, GM, HC, Rock                           | Wet Loose Surface Road        | 300      |

The CCTT ground vehicle mobility model treats stemmed vegetation and localized terrain obstacles (e.g., anti-tank ditches) as discrete objects which are handled by either maneuvering (avoidance) or an obstacle-specific movement algorithm. Snow is not currently modeled in CCTT.

## 4. WARSIM Trafficability

### 4.1 Background

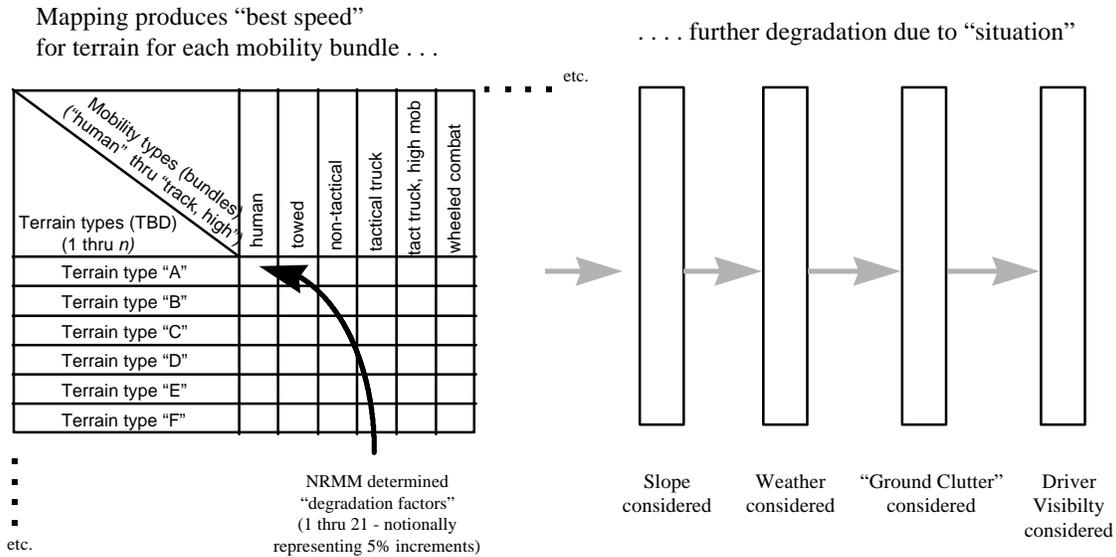

WARSIM (Warfighting Simulation) is a simulation developed for the purpose of training U.S. Army commanders and their staffs from a battalion through a theater level war. The level of fidelity in modeling ground vehicle mobility considers platform-level issues, however a large amount of behavior will be aggregated to the platoon level. The reasons for the platform representation of movement are multiple. First, the mobile capability of individual platforms within a group must be considered (requiring explicit calculation) when deciding on a commanded speed for the group. In addition, platforms must appear “tactically” correct—moving platforms must keep a commanded speed, formation and avoid obstacles. Also, since targeting of individual platforms will occur, individual platforms may be lost from the parent unit due to attrition and casualties. Each moving platform must be accounted for within the WARSIM infrastructure with a specific location, and sensors must be able to track platform-specific information during the simulation. An abstract platoon object is used to direct the corresponding movement components of an “equipment group” and tasks common to all constituent platforms are handled by this object. An example is one platoon following another platoon on a route – a basic road march order.

The WARSIM ground vehicle mobility model is similar to emulated-driver vehicle models as used in platform-level CGF simulations (e.g., ModSAF). It has significantly reduced fidelity requirements from human driver trainers, and is specifically required to run at “faster than real time” speeds – a critical requirement for most aggregate-level simulations.

The model has been tweaked subsequent to its initial development, so the following descriptions may not exactly correspond to a particular implementation.

### 4.2 Model Overview

The WARSIM ground vehicle mobility model is derived from the NATO Reference Mobility Model II (NRMM II; see Section 5, below). Performance concerns resulted in a design based on table look-up. Many of the detailed inputs needed for the NRMM II are inferred, simplified, or aggregated to reduce the amount of data produced in the form of “speed reduction factors” or SRFs for the various representative mobility bundles within WARSIM. The overall design is as illustrated in Figure 5.

**Figure 5:** WARSIM mobility model data flow

WARSIM represents more than 200 towed, wheeled, or tracked ground mobility platforms. In order to define their ground mobility capabilities without obtaining a complete set of all the required inputs needed for the NRMM II for each platform, platforms with similar characteristics are grouped or categorized into nine bundles as listed in Table 13. A representative vehicle is used to representing the mobility capability of each bundle.

**Table 13:** WARSIM Mobility Bundles and associated Representative Vehicle

| WARSIM Mobility Bundle  | Representative Vehicle  |
|-------------------------|---|
| Low-mobility Towed      | M911 with M747 heavy equipment transporter (HET) trailer              |
| Medium-mobility Towed   | M923, 5-ton Truck towing an M1061, 1 ½ ton trailer                    |
| High-mobility Towed     | Medium Tactical Vehicle (MTV, like the M1084) towing an M1061 trailer |
| Low-mobility Wheeled    | M911 HET  |
| Medium-mobility Wheeled | M923, 5-ton Truck   |
| High-mobility Wheeled   | MTV   |
| Low-mobility Tracked    | Armored Vehicle Launched Bridge                                       |
| Medium-mobility Tracked | M113A3 Armored Personnel Carrier                                      |
| High-mobility Tracked   | M1A1 Main Battle Tank   |

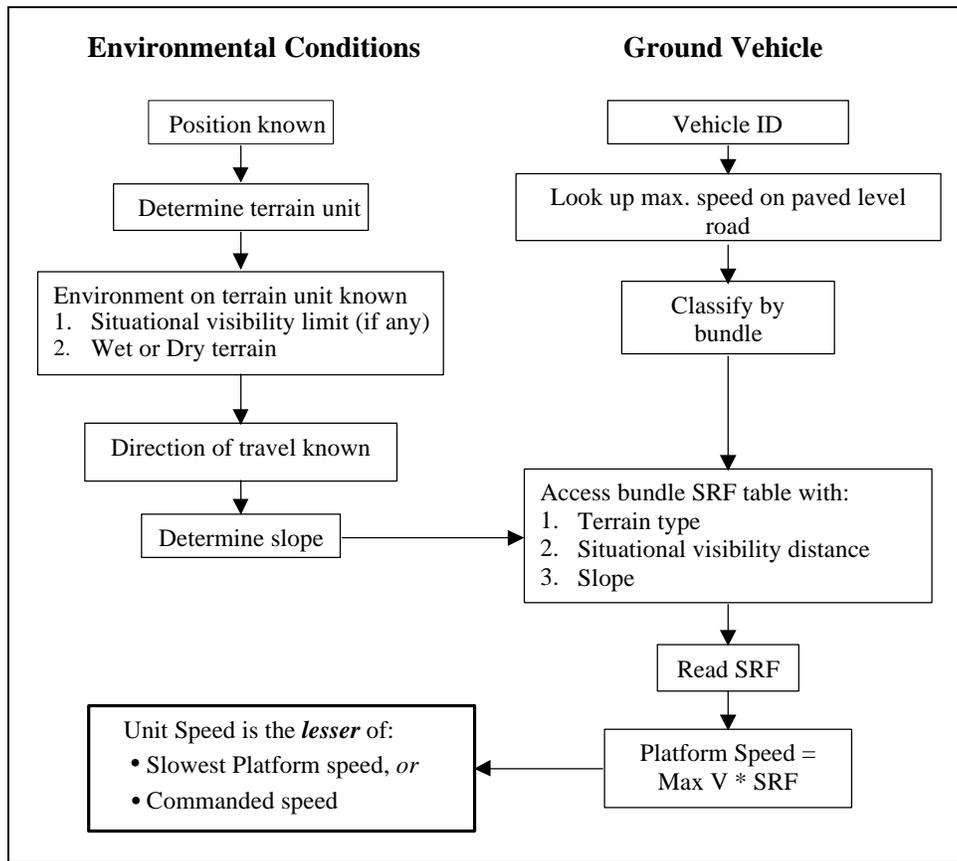

The bundles are defined by the uniform application of the speed reduction factors (SRF) produced from running the NRMM II against a representative vehicle or representative combination of trailer and prime mover for the “towed” bundles. The appropriate SRF is applied to each platform’s maximum road speed to determine the “best speed” which that platform could physically achieve in its current conditions. The “best speed” may vary between platforms belonging to the same mobility bundle, if their baseline maximum speeds are different.

The speed reduction factors (see Figure 1) are pre-computed using NRMM II for the representative vehicle for each mobility bundle under multiple conditions. These conditions are:

- Slope: 8 bands from “minus” (-)40% to “plus” (+)40 % including zero slope or level ground.
- Surface condition: 2 values – wet and dry.
- Obstacle spacing: 4 values – “no clutter”, 30 feet, 25 feet, and 20 feet.

- Situational visibility: 4 values – unlimited, 100 feet, 50 feet, and 25 feet.

Figure 6 illustrates how the environmental conditions, the ground vehicle, and the commanded speed relate to each other.

**Figure 6:** WARSIM Abstract Mobility Model Logic Diagram

The terrain type stored in the runtime terrain database is termed the “Surface Trafficability Group, JSIMS Mobility Model (STGJ)”, and is defined as: “The index used by the US DoD Joint Simulation System (JSIMS) to describe the trafficability of a terrain unit with respect to ground forces. This value is used to index one or more lookup tables associated with the ground forces mobility model in order to predict or analyze ground force movements (e.g., units, vehicles, infantry).” There are 807 individual types recognized (see Section 4.4), however these are currently mapped to a smaller set of 255 types for use in indexing the SRF table.

Figure 7 summarizes the WARSIM system-level approach to ground vehicle mobility modeling using offline lookup table generation, runtime lookup, and multiplicative degradation for weather and soil moisture.

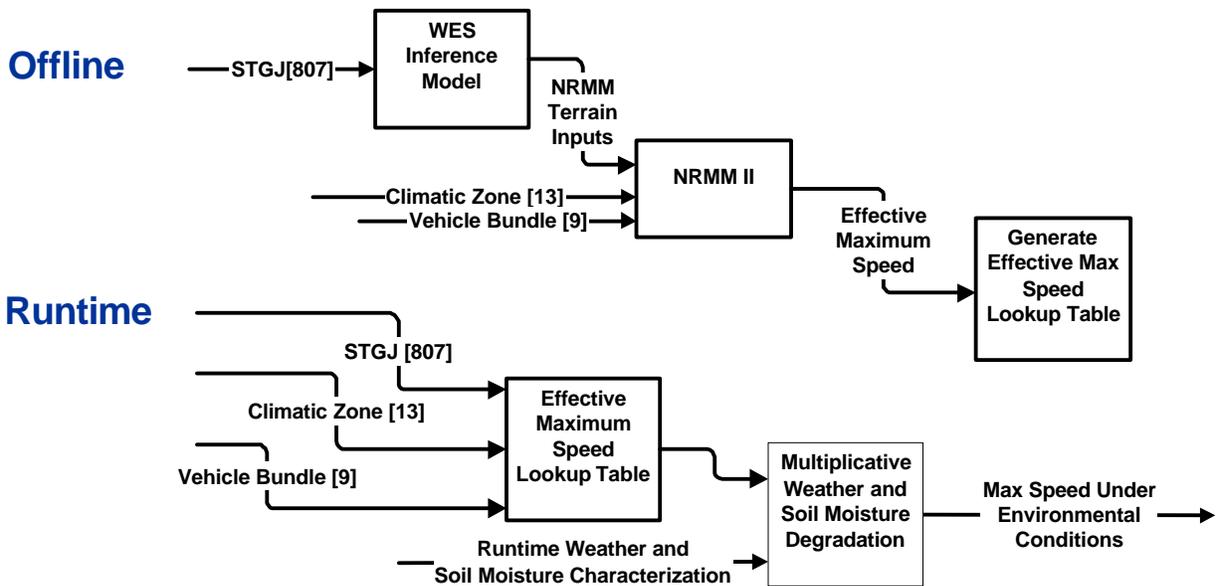

Figure 7: WARSIM System-Level Mobility Model Data Flow

### 4.3 Slope

The WaRSIM ground vehicle mobility model defines 8 slope classes (see Section 4.2). Each class represents a range of slope values along the direction of vehicle travel, and is treated as a single representative slope in the SRF table.

### 4.4 Trafficability

The WARSIM ground vehicle mobility model defines 807 terrain codes (see Table 14) for modeling ground vehicle mobility. Each terrain code denotes a unique combination of feature type (if applicable), surface type (generally soil), the presence and type of vegetation (including crops as well as brush/undergrowth), and the presence of unique landforms (e.g., sand dunes).

Table 14: WARSIM Terrain Codes

| Code | Definition                                   |

## 5. NATO Reference Mobility Model II

### 5.1 Background

The NATO Reference Mobility Model (NRMM) was developed in the early 1970's and combines many mobility related technologies into one comprehensive package designed to predict the physically constrained terrain/vehicle interaction of vehicles operating in on- and off-road terrain. Since its inception NRMM has been continually updated and expanded as a result of ongoing mobility research and is now in its second release (NRMM II). NRMM provides NATO members with a standard reference for mobility performance evaluations. NRMM is integrated into other automated models providing the mobility predictions for several tactical, analytical and wargaming models.

NRMM is an example of a "traditional" mobility model that ignores driver inputs (mostly) and assumes either maximum throttle or maximum braking in order to determine "maximum speed made good". Such models are often used in command and control decision aids where the objective is to predict general rates of movement rather than specific vehicle performance in the hands of a (skilled) human operator.

### 5.2 Model Overview

NRMM is a force balance model. A theoretical maximum tractive force versus speed relation is determined from characteristics of the vehicle power-train, the ground traction assemblies, and the terrain surface characteristics. Then various resisting factors which produce impediments to motion are determined. The sum of these resistances compared with the tractive-force versus speed relation provides a maximum possible force-controlled speed. Several non-force related speed limits are determined. The minimum of these speeds and the force controlled speed are compared to yield a final (steady state) maximum vehicle running speed. Then this vehicle running speed is considered in conjunction with the frequency of occurrence of individual terrain elements within a given area to provide a final "speed made good".

NRMM is comprised of several sub-models each of which contributes to some aspect of ground mobility performance and, in many cases, has been developed as a result of scientific laboratory and field studies. Many of the sub-models are empirical while others are more theoretical. A study specifically designed to validate the comprehensive model resulting from the logical combining of these sub-models has been performed. Since its inception NRMM has been further validated by the continual ongoing vehicle mobility studies conducted at the U.S Army Waterways Experiment Station (WES) and other Army laboratories.

NRMM consists of the following major components:

- a sub-model to predict the power train performance,

- a vehicle/surface interface routine (soils & hard surfaces),
- a slope effects sub-model (lateral and longitudinal),
- an obstacle-geometry/vehicle interface sub-model (macro-geometry),
- a ride dynamics response sub-model (micro-geometry),
- a vehicle/vegetation interface sub-model,
- a braking performance sub-model, a curvature sub-model,
- a water crossing sub-model (currently disabled due to lack of acceptable input terrain data), and
- several other routines which have minor influence on the results.

There are several related mobility prediction models which are not part of the official NRMM family, but which are included in the related suite of analytical prediction programs:

- a swimming criteria prediction program (SWIMCRIT) provides dry and water-filled gap predictions. Does not predict speed; only GO / No-GO based on traction and resistance;
- a tracked vehicle steering (TVSTEER) model provides information about steering for tracked vehicles. This model is still under development and has not been fully validated; and
- a wheeled vehicle steering model is under development.

A full description of the NRMM ground vehicle mobility model is beyond the scope of this document. Additional documentation can be found in the following references:

### **5.3 Slope**

The NRMM ground vehicle mobility model uses continuously varying up and down slope values along the direction of vehicle travel. Lateral slope is generally ignored.

### **5.4 Trafficability**

Table 14 lists the feature types and their associated attributes that are used as terrain trafficability inputs by NRMM II. A complete data model, including the domain range for each feature-attribute combination, is available.

**Table 14: NRMM II Features and Associated Attributes**

| <b>BRIDGE</b><br>(line)                | A <STRUCTURE> that connects two <LOCATION>s and carries pedestrian or <VEHICLE> traffic over a <TERRAIN_OBSACLE> such as a <WATER_BODY>, a declivity, or a <ROAD>; a bridge, an overpass. |
| <i>Attribute Set</i>                   |   |
| BLOCKAGE_PRESENT                       | LOAD_CLASS_ONE_WAY_TRACKED  |
| LOAD_CLASS_ONE_WAY_WHEELED             | LOAD_CLASS_TWO_WAY_TRACKED  |
| LOAD_CLASS_TWO_WAY_WHEELED             | OVERHEAD_CLEARANCE  |
| VEHICULAR_SPEED_LIMIT                  |   |
| <b>CROSS_COUNTRY_BARRIER</b><br>(line) | A permanent or semi-permanent <BARRIER> placed across any <TERRAIN> to prevent <VEHICLE> or <PERSONNEL> traffic.  |

<sup>9</sup> Attributes (and Features) are denoted by their EDCS EA and EC Labels, respectively.

<sup>10</sup> EDCS label notation has been extended through use of the “qualified by” syntax (“QB”) which composes two EDCS attributes such that the result is a primary attribute with multiple values indexed by the domain values of the second attribute; for example, MEAN\_STEM\_SPACING as a function of STEM\_DIAMETER, and SOIL\_CONE\_INDEX as a function of MEASUREMENT\_DEPTH.

| <i>Attribute Set</i>                 |                                    |

**Author Biography:**

**PAUL A. BIRKEL** is a senior principal scientist for The MITRE Corporation. He currently provides technical support and guidance to the National Mapping and Imagery Agency (NIMA) in the area of terrain data standards, the DMSO Synthetic Environment Data Representation and Interchange Specification (SEDRIS) project, the US Army Environmental Data Base (EDB) Integrated Product Team (IPT), and the US Army Urban Science and Technology Objective (STO). In addition he provides guidance and support as needed to other DoD M&S and C<sup>4</sup>ISR programs via the US Army Topographic Engineering Center (USATEC).
